16 Abstract

The overall goal of the PLAY (Play & Learning Across a Year) project is to catalyze 17 discovery about behavioral development in infancy. PLAY will focus on the critical period 18 from 12 to 24 months of age when infants show remarkable advances in language, object 19 interaction, locomotion, and emotion regulation. PLAY will leverage the joint expertise of 63 "launch group" researchers, and capitalize on the Databrary video-sharing library and 21 Datavyu video-coding tool to exploit the power of video to reveal the richness and 22 complexity of behavior. Together, PLAY researchers will collect, transcribe, code, share, and 23 use a video corpus of infant and mother naturalistic activity in the home to test behavioral, developmental, and environmental cascades. The project will demonstrate the value and 25 feasibility of a cross-domain synergistic approach, and advance new ways to use video as documentation to facilitate discovery and ensure transparency and reproducibility. 27

Examining play and learning across a year: The PLAY Project

30

Behavior lies at the heart of developmental science, and video is a uniquely powerful 31 tool for capturing the richness and complexity of behavior 2,3. Video documents the 32 microstructure of behavior in real time and global patterns of change over development 4,5—a 12-month-old's single-word reference to a dog versus a 24-month-old's multi-word declarative ("big doggie eat"). Video chronicles who did what, and how, when, and where they did it6—whether the dog was big, eating, jumping, or barking, whether the child looked at the dog, touched the dog, shied away from or approached the dog, and expressed interest, fear, or joy. 38 The overarching goal of the PLAY (Play & Learning Across a Year) project is to 39 exploit the power of video to catalyze discovery and transform knowledge about behavioral 40 development in infancy. The project capitalizes on the NICHD/NSF-funded Databrary 41 video-sharing library and the Datavyu video-coding tool developed by PIs Adolph and Gilmore, and the joint expertise of 63 PLAY "launch group" researchers in the United States and Canada (see BIOSKETCHES and LETTERS OF SUPPORT). To do so, we will create the first, large-scale, sharable and reusable, transcribed, coded, and curated video corpus of human behavior. And we will advance new video-based means of documentation to increase transparency and reproducibility in behavioral science. We named the project "PLAY" and use "unstructured play" and "everyday play" to 48 broadly refer to infants' natural activities while awake. To paraphrase Piaget9, Montessori10, and Bruner11,12, play is the work of infants. It is an approach to action, not a particular form of activity. Some of infants' play involves toys and some play is joyful and goal directed, but all of their spontaneous vocalizations, interactions with objects and people, and locomotor bouts involve exploration and opportunities for learning and growth, regardless of affect or intent.

The project has three aims: 1. To create the first cross-domain, large-scale, transcribed, coded, and curated video corpus of human behavior—collected with a common protocol and

coded with common criteria; 2. To answer fundamental questions about behavioral and
developmental cascades; and 3. To demonstrate the scientific value, feasibility, and
scalability of a synergistic approach to collaborative research, and advance new ways to use
video as documentation to ensure transparency and reproducibility. In this paper, we
describe the process of planning PLAY, our preliminary results from a pilot study, and plans
for a larger scale implementation.

Project Planning

63

Planning began in late 2015. Adolph, Tamis-LeMonda and Gilmore (PLAY PIs) 64 invited researchers to join the launch group based on their interest in open science and 65 infant-mother natural activity in the home, willingness to collaborate on data collection and coding, lab location, and domains of expertise (language, gesture, play, object exploration, 67 tool use, locomotion, posture, physical activity, emotion, temperament, parent responsiveness, gender, home environment, media use, spatial demography, and sampling). Nearly every invite agreed. The launch group contains 32% young/new investigators, 66% 70 women, 19% non-white, from varied institutions (public and private universities and colleges, 71 hospitals, agencies) with varied resources (62% public universities, 19% R15-eligible institutions) across the United States and Canada. Each has committed to produce at least one research study based on the video corpus. To distribute the burden of video coding across researchers, the PLAY PIs recruited 75 10+ experts for each of four core coding passes—communication, object interaction, 76 locomotion, and emotion. These domains represent key areas of development and provide 77 foundational information when time-locked to video. Compared with other behaviors (e.g., visual attention), they are quick, easy, and reliable to code. 79 Through a yearlong series of telephone conversations with each launch group member 80 and 12 group webinars, we jointly developed a common sampling method and protocol 81 (including materials, technical specifications, questionnaires, and non-video measures),

designed common video codes, and established an infrastructure to divide responsibilities
between PLAY staff and launch group. We achieved consensus, with input from NICHD
program staff, about all aspects of PLAY at a daylong workshop shared on Databrary56, at
NIH in Dec 2016.

The launch group jointly decided that the centerpiece of PLAY would be 900 one-hour videos of infant-mother dyads during natural play in the home. Home videos are widely believed to be representative of natural activity, and provide a stark contrast to the 2- to 20-minute "snapshots" typical of standard structured lab tasks. Based on their extensive experience with naturalistic home observations 43,44,46,57-61, launch group members determined that one hour is sufficiently long to capture an ecologically valid window into infant and mother natural behaviors. Longer recording times produce diminishing returns, risk infants becoming excessively tired or hungry, and increase the cost and burden to families and researchers.

Given the cost of going to families' homes, the launch group also determined that we should augment natural play with a set of additional video, questionnaire, and non-video measures, that together would add only ~45 minutes to the home visit. This would enable researchers to test whether variations in natural play, or in characteristics of distal and proximal environments, predict infant and mother behaviors when materials and conditions are held constant. Thus, the solitary and dyadic play tasks are of interest in their own right, and might also serve as correlates in tests of experiential and environmental influences.

To obtain objective data on stable home conditions (cracks in walls, broken windows, ceiling stains, safety issues, etc.), physical layout (furniture, clutter, space to move, etc.), educational and electronic media (writing/drawing materials, TVs, computers, etc.), and gendered characteristics of infants' room, toys, and clothes, we decided to conduct video home tours. Launch group experts also expressed interest in understanding whether clothing and footgear affect infants' locomotion and physical activity, and each takes only moments to video record. Clothing/footgear videos can reveal gendered features (bows/frills, superhero

emblems, patent leather shoes, army boots)66 and influences on spontaneous activity and 110 locomotion 67. The launch group also deemed important a variety of questionnaire measures 111 of infant skills, experiences, and home environment: mothers' report of infants' vocabulary, 112 locomotor milestones and falls, temperament, and use of gender labels; mother's report of 113 family demographics, media use, health, and home chaos; and a researcher-completed survey 114 on physical characteristics of the home. The PIs developed a custom tablet-based app to 115 collect these questionnaire data efficiently, limit data input errors, use a stylus for flexible 116 data entry, and allow automatic transfer to permanent storage on Databrary. The launch 117 group devised methods to measure room size with a commercial laser device and ambient 118 noise level with a commercial decibel meter. 119

Finally, with input from the launch group, we decided to transcribe all mother speech and infant vocalizations in formats exportable to CHILDES. The launch group also developed "foundational," time-locked codes of infant and mother behaviors in four core domains (communication/gesture, object interaction, locomotion, emotion). These codes should be informative even to non-experts and are designed to facilitate further discovery through subsequent coding passes that build on the prior work. Temporally aligned transcriptions and codes should enable researchers with expertise in any domain to analyze cascades within and among these behaviors.

Pilot Study

Based on the launch group's recommendations, we carried out a pilot study to test the feasibility of the approach.

31 Methods

128

A publicly-accessible wiki [?] was used to document all procedures and code definitions.

The wiki50 that links descriptions of every aspect of the protocol with exemplar third-person video clips (e.g., researcher scheduling home visit). The wiki will also link descriptions of each code to video clips illustrating the types of behaviors that do and do not satisfy the

coding criteria. These ways of using video as documentation are innovative, yet simple and inexpensive to produce, and will serve as a proof of concept for increasing transparency and reproducibility.

Video as documentation cites

139

Participants. A total of n = 20 infants were tested, n = 4 12-month-olds (3 female), n = 12 18-month-olds (5 female), and n = 4 (0 female). All were from the New York City area. Fifteen infants were White, one was Asian, two reported more than one race, and two did not report a race. Six were of Hispanic or Latino ethnicity.

Procedure. The PIs designed a wiki50 to aid training, ensure fidelity to the protocol and codes, and provide complete transparency (Figure 2). The wiki documents the entire data collection protocol, all video-based measures including transcription and code definitions, and all questionnaire and non-video measures. It uses photos and video exemplars to make text-based descriptions clear and transparent. The wiki makes cross-site training consistent and cost-efficient and ensure that future researchers can reproduce our protocol with high fidelity.

The PIs also established that transcription in English or Spanish takes 7-9 hours per hour of video. All four foundational coding passes are easy to learn (by undergraduate coders on Datavyu) and time efficient (< 3 hours for both infant and mother for each coding pass per hour of video). Note, both infant and mother communicative acts and gestures together take < 3 hours to code.

Data analysis. For this report, we used R (Version 3.4.4; R Core Team, 2017b) and the R-packages acs (Version 2.1.3; Glenn, 2018), bindrcpp (Version 0.2; Müller, 2016), choroplethr (Lamstein, 2017; Version 3.6.1; Lamstein & Johnson, 2017), choroplethrMaps (Version 1.0.1; Lamstein, 2017), dplyr (Version 0.7.4; Wickham & Francois, 2016), forcats (Version 0.3.0; Wickham, 2018a), foreign (Version 0.8.69; R Core Team, 2017a), Formula (Version 1.2.2; Zeileis & Croissant, 2010), gpplot2 (Version 2.2.1; Wickham, 2009), gmodels (Version 2.16.2; Warnes et al., 2015), googlesheets (Version 0.2.2; Bryan & Zhao, 2017),

Hmisc (Version 4.1.1; Harrell Jr, Charles Dupont, & others., 2017), httr (Version 1.3.1; 163 Wickham, 2017a), jsonlite (Version 1.5; Ooms, 2014), lattice (Version 0.20.35; Sarkar, 2008), 164 MASS (Version 7.3.49; Venables & Ripley, 2002), multilevel (Version 2.6; Bliese, 2016), nlme 165 (Version 3.1.131.1; Pinheiro, Bates, DebRoy, Sarkar, & R Core Team, 2017), papaja (Version 166 0.1.0.9709; Aust & Barth, 2017), plyr (Wickham, 2011; Version 1.8.4; Wickham & Francois, 167 2016), psych (Version 1.7.8; Revelle, 2017), purr (Version 0.2.4; Henry & Wickham, 2017), 168 readr (Version 1.1.1; Wickham, Hester, & Francois, 2017), stringr (Version 1.3.0; Wickham, 169 2018b), survival (Version 2.41.3; Terry M. Therneau & Patricia M. Grambsch, 2000), tibble 170 (Version 1.4.2; Wickham, Francois, & Müller, 2017), tidyr (Version 0.8.0; Wickham, 2017b), 171 tidyverse (Version 1.2.1; Wickham, 2017c), and XML (Version 3.98.1.10; Lang & CRAN 172 Team, 2018) for all of our statistical analyses. Datavyu [?] was used for video coding. All 173 code used in data analysis and for this manuscript may be found in the GitHub repository associated with the paper [?]. 175 To compute inter-observer reliability, we ran scripts in Datavyu to selects a random 176 segment of video (25% or 5 mins) from each 20- minute segment of natural play. 177 Inter-observer reliability for the pilot videos was 96.7%-99.3% exact frame agreement 178 (kappas > .93, ps < .001) for duration codes (object interactions, locomotion, emotion) and 179 94.1%- 99.5% code agreement (kappas > .89, ps < .001) for categorical events 180 (communicative acts, gesture). 181

182 Results

Informal inspection of the videos verified that dyads were unaffected by the presence of
the researcher: After a few minutes of acclimation prior to natural play, mothers and infants
ignore the researcher. Infants cry and breastfeed; mothers yell, talk on the phone, work on
computers, go about daily chores, change infants' diapers, and give infants snacks. The PIs
verified the efficiency of the new custom tablet app for collecting questionnaire data.

Mothers appeared comfortable with all procedures, including the video home tour. The PIs

found wide variation in home "disarray," suggesting parents present homes as they would for any other casual visitor. 27 of 28 mothers agreed to share data. Pilot testing verified the feasibility of collecting all data in < 2 hours. So, with 1-2 hours of round-trip travel time, the entire data collection can be completed in < 4 hours.

For space reasons, we only summarize here the ambient sound level data and depictions of the foundational video coding passes.

Ambient sound levels.

Video coding.

197 Discussion

195

196

200

201

The pilot study verified that the protocol met the launch group's criteria on scientific and practical grounds. So we proceeded to design and plan a full-scale implementation.

Proposed study

The proposed study builds upon and extends the pilot study.

202 Methods

The same publicly-accessible wiki [?] will be used to document all procedures and code definitions.

Participants. We plan to collect data from n = 900 infant-mother dyads from 30 different communities in 17 states located around the U.S. Each site will collect data from 30 infants, 10 each at 12-, 18-, and 24-months of age (+/- 1 week), with equal numbers of females and males. Figure ?? shows the proposed data collection sites and non-collecting, data coding and analysis sites.

While not designed to be nationally representative, the data collection sites are diverse
in aggregate, based on Census data. ?? shows the proportion of African American,
Hispanic/Latino, and Asian residents in the counties surrounding the collection sites from
which participating researchers will recruit. Figure ?? and Figure ?? show economic and

educational attainment indicators. Data collection sites will have soft, advisory recruiting targets based on these sorts of measures for their individual communities.

To gather Census data reproducibly, we used the **chorplethr** package to download data from the Census Bureau's public API. This workflow allows us to easily gather and analyze other Census Bureau data about the communities targeted for sampling.

Families will be two-parent, English and/or Spanish speaking households with resident 219 fathers, with both parents >18 years old. Infants will be term firstborns, without birth 220 complications or disabilities, and 12, 18, or 24 months of age (± 1 week); half of infants at 221 each age and site will be boys. We chose these ages because 12- to 24-months represents a 222 period of important, rapid growth when children begin talking, using objects in symbolic 223 play, walking, and regulating emotions. For example, by 12 months, about half of infants can 224 walk and half still crawl. By 18 months, infants are proficient walkers, and by 24 months, 225 they can run, walk backwards, and walk up stairs 16,17. Around 12 months, infants produce 226 their first words. By 18 months, most display a vocabulary spurt, and by 24 months infants 227 combine words into simple sentences 13,14. But these ages represent only group averages; 228 individual infants show tremendous variability in these behaviors at each age. 229

The sample is not intended to be nationally representative. The launch group 230 deliberated over several sampling strategies 27,69,70. Informed by experts in the launch 231 group, we decided on homogeneous sampling to contain costs and understand behavioral 232 variation. Homogenous sampling maintains some control over sample characteristics through 233 a set of inclusionary criteria (here, firstborn status, English/Spanish home language, term 234 pregnancy, etc.), while maximizing select aspects of diversity (e.g., geography, SES) and 235 retaining sufficient power for group comparisons. We ruled against conventional convenience sampling, which leaves sampling decisions entirely to researchers' discretion. Although 237 convenience sampling is easy and cost efficient, it risks yielding a sample that varies on too 238 many demographic dimensions to control. At the other extreme, population-based 239 (probability) sampling is cost-prohibitive due to the required sample size. The sheer volume

of data would prohibit transcription and video coding, and would require hiring and training special researchers for data collection, rather than relying on the existing expertise of the launch group.

Procedure. During an initial screening call, a researcher will determine eligibility for participation, and obtain demographic information. The researcher will schedule a 2-hour visit (weekday or weekend) when infants are between naps, meals, and baths, and would normally be home with their mothers. At the end of the visit, the researcher will ask mothers if the one-hour natural play session was representative of a typical day at home. If mothers report that infants' behavior or health was atypical, we will replace the dyad and document the replacement.

The visit will include, in order, parent consent, one-hour natural play, two structured 251 play tasks, questionnaires, video home tour, and Databrary sharing permission. Although 252 mothers will agree to share data in the initial screening call, we will request their signed permission at the end of the home visit when they are maximally informed. Consent, sharing 254 permission, and questionnaire data will be entered on the custom app; paper forms and 255 video camera on tripod will provide backup. Based on the pilot study, and our own 256 experience in other studies, we anticipate that most families agree to share data. If families 257 decline to share, their data can still be stored on Databrary and used by the collecting 258 researcher for their own purposes. 250

Natural play: Like the pilot, we will record one hour of infant and mother activity in
the home. Infant and mother will go about their daily routines without restrictions. They
can move from room to room; mother can do chores; TV, music, or other media can be on.
All of these behaviors were common in our pilot data. The researcher will hand-hold an HD
video camera at the child's eye level, prioritizing view of infant over mother, keeping the
infant's face, hands, and feet in view. If mother is visible, the researcher will capture as
much of her face and body as possible without losing view of the baby. A cardioid
microphone will amplify infant and mother speech and isolate background noise. Home visits

²⁶⁸ avoid the artificiality of unfamiliar lab environments, materials, and tasks, and therefore ²⁶⁹ come closest in fidelity to infant and mother natural behavior.

We will take several precautions to minimize effects of experimenter and camera presence on dyads72,73. We will train researchers to remain unobtrusive. They will stay at a distance, resist talking to mother or infant, and watch the infant through the viewfinder to avoid eye contact. Filming will begin after several minutes of infant-mother acclimation to the camera and researcher.

Solitary play will entail infants playing with a set of 10 nesting cups (placed half up, 275 half down) while sitting on a mat with mother nearby but not interacting (2 minutes). 276 Nesting cups can reveal developmental differences in attention, manual action, spatial 277 problem solving, and symbolic play. Younger pilot infants manually explored the cups but 278 had difficulty nesting consecutive sizes; older pilots nested cups and used them symbolically 279 (e.g., pretended to drink). In dyadic play infant and mother will play together on the mat 280 with a standard set of toys (3 minutes)—truck, doll, baby bottle, small blanket, 2 tea cups, 281 plates, and spoons—with mother instructed to "share the toys with her child." The toys are 282 conducive to non-symbolic (stacking plates, cups), symbolic (feeding doll, putting doll to 283 sleep), and gendered play (with truck versus doll).

Following the play episodes, the researcher will walk through each room, filming walls,
floors, ceilings, windows, room contents (including infants' toys, books, media), and the
contents of infants' closets and drawers. The mother will name each room, describe infant's
access to rooms and spaces, and open closet doors and drawers for filming. Prior work and
piloting ensured that mothers did not find this procedure intrusive. The researcher will
narrate the video with comments about floor coverings ("throw rug," "linoleum") and
anything not transparent to video.

During the visit, the researcher will record the clothes (front and back) and footgear
(bottom, side, top) infants wore during the natural play session, and record the date infants
began wearing the shoes and for how many days/week infants play indoors in shoes, socks,

295 and barefoot.

After the naturalistic and structured play tasks, the researcher will interview mothers
on a range of infant and family measures that will yield information about language,
locomotion, temperament, gender, home environment, and health (Table 2). The researcher
will administer all questionnaires orally, and video records the interview (camera on tripod)
for quality assurance, transparency, and possibly later coding.

Language (QL1): We will use the 12-month (words and gestures) and 18- to 24-month 301 (words and sentences) versions of the MacArthur-Bates Communicative Development 302 Inventory (MCDI). The MCDI is the most widely used instrument of infant language 303 development, administered to over 60,000 children in 23 languages 75. The 12-month MCDI 304 measures receptive and expressive vocabulary size and communicative gestures; the 18- to 305 24-month version contains a larger set of vocabulary items and simple sentence constructions. 306 NL2: Mothers will report the language(s) spoken to infant by parents and childcare workers. 307 Locomotion (QM1): Mothers will report the onset ages of hands-knees crawling and walking, 308 using cell phone videos, photos, and diaries to jog their memories 76,77. QM2: Mothers will 300 report on infants' fall-related injuries. Infant temperament (QE1) will be indexed with the 310 Rothbart Early Childhood Behavior Questionnaire (ECBQ), very short form 78,79, which 311 measures dimensions of surgency, negative affect, and effortful control. Gender (QG1): 312 Mothers will report infants' use of gender labels (e.g., boy, girl) to refer to themselves or 313 other people. QG2: Mothers will report their own and the father's attitudes to gender 314 normative behavior (e.g., "I would be upset if my son wanted to dress like a girl"); and 315 household division of labor (e.g., who does cooking). Environment (NH1): Ambient noise will be measured during natural play with a decibel meter, placed in the main room, to 317 record peak and average dB every 100 ms. NH2: In the home video tour, the researcher will 318 measure room dimensions with a laser distance measurer. QH3: At the end of the visit, the 319 researcher will fill out a survey on the home environment (from launch group member 320 Evans). QH4: Mothers will report use of electronic media (TV, computers, apps, etc.) by 321

infant and family members (from launch group member Barr). Health (QF1-4): Mothers will report infant, parent, and family demographics, infants' health history (based on a subset of questions from the ECLS-B 9-month and 2-year interviews), childcare experience, and parents' and family health history including SLI, ASD, and mental illnesses.

Transcriptions and four core coding passes will be scored for both Video coding. 326 infant and mother. PLAY staff will transcribe speech at the utterance level, using standard 327 criteria for segmenting speech 74. Utterances will be defined by independent clauses 328 (statements with subject and predicate) with modifiers. Intonation and pauses can also 329 define breaks (e.g., "You like that . Right?" is two utterances). Mothers' language-like 330 sounds are typed out phonetically. Infant babbles are marked with "b" and non-linguistic 331 vocalizations (cry, laugh, grunt) with "c." Unintelligible utterances are marked "xxx." 332 Utterances will be time-locked to video, revealing overlaps in infant-mother speech, and 333 co-occurrence and sequencing of speech with object interactions, emotions, and locomotion. 334 Spanish transcriptions will follow the same rules. 335

Based on transcripts, mothers' utterances will be coded as declaratives (labels and 336 descriptions of objects and events "Red"; "Puppy"), attention-imperatives that solicit infant 337 attention ("Look at that"), action-imperatives that solicit infant action ("Put it there"), or 338 prohibition-imperatives ("Stop it!"); interrogatives (open- and close-ended questions, "Is it 339 hot?" with the exception of "tag" questions, which will be coded as declaratives, "That's a 340 ball, right?"); affirmation/conversational fillers ("Yes!"; "What's next?"), and unintelligible. 341 Infants' vocalizations will be categorized as language (sentences or words), prelinguistic 342 vocalizations (babbling or vowels), non-linguistic vocalizations (e.g., cry, laugh, scream, 343 grunt), or unintelligible. 344

Gestures will be categorized as points, show/hold up (deictic), conventional (wave bye-bye, thumbs-up), and representational (flapping arms to represent a bird).

Object interactions will be coded for onset and offset of manual engagement (touching, manipulating, carrying) with any manipulable, moveable object or part of an object that

moves through space. Locomotion will be coded for onset and offset of self-generated locomotion of any form (e.g., crawling, walking, climbing, stepping in place). Coders also score falls, and periods when the infant is held or constrained by furniture (e.g., highchair). Emotion will be coded for onset and offset of positive (smiling, laughing) and negative (crying, frowning, fussing) facial expressions. Inter-observer reliability:

To verify inter-observer reliability, PLAY staff will rescore 25% of each infant's natural play video (5 minutes randomly drawn from each 20-minute segment), blind to the original coders' output (categorical measures: kappas >.85; duration measures: % exact frame agreement > 90%). If codes are not reliable, PLAY staff will reassign the videos to a new lab.

Data analysis. The launch group will jointly establish best practices for PLAY analyses. Our guidelines will include: recommendations to pre-register predictions and analyses; the use of procedures that use one portion of the data set to explore correlations among variables and a separate subsample to confirm it; the use of reproducible and transparent workflows for data processing and analyses (e.g., Ruby scripts in Datavyu; syntax instead of menu-driven commands for SPSS users; scripts and functions for R users); a commitment to openly sharing supplementary video codes and operational definitions to avoid unnecessary duplication of coding efforts; and open sharing of null results as well as positive findings. We will create means for communication (e.g., a Google group) among launch group members who wish to discuss, propose, and organize team efforts focused on answering specific video-based research questions. In addition, we intend to report how we determined our sample size, all data exclusions (if any), all manipulations, and all measures in the study.

General Discussion

The PLAY corpus will be a treasure trove of data, and it will all be made available openly to the research community at the end of the study. Our hope is that it will seed substantial new scholarship.

Researchers can examine real-time behavioral cascades among infant behaviors, among 375 mother behaviors, and between infants and mothers. They can test whether particular infant 376 behaviors are temporally connected (e.g., vocalizations and gestures) or independent 377 (vocalizations and locomotion). They can test infant-to-mother cascades and vice versa, such 378 as whether infant emotional expressions affect real-time language input from mother. Prior 379 correlational work, for example, shows that infants who express higher quantities of negative 380 emotions display lower levels of language development on the MCDI and later language 381 milestones 37,80. But the evidence for these findings offers limited insight into the real-time 382 behaviors that underlie the correlations 81. With PLAY, researchers can examine real-time 383 behavioral cascades by testing whether infants' negative emotions (Table 1 VE1) hinder 384 interactions with objects (Table 1 VO1) and/or vocal and gestural communications (Table 1 385 VL2-3), and consequently, lead to low quantity and diversity of mother speech (Table 1 VL1-2). Infant emotions could also facilitate language learning: Emotional expressions might 387 elicit mental state terms and emotion words from mothers (e.g., "You think mommy's leaving?", "Why are you sad?"). Regardless, whether and how infant emotions affect their 389 language development requires data on the words mothers use preceding, during, and 390 following infant emotional behaviors in real time.

PLAY's three age groups and measures of skill and experience (e.g., MCDI, walking 392 experience) allow researchers to investigate developmental cascades in new ways. We can 393 examine age-related changes in temporal coordination among infant, mother, and 394 infant-mother behaviors—such as whether infants of different ages with different skills elicit 395 different behaviors in mothers. For example, object interactions in 12-month-olds, who are typically at the cusp of conventional word use, might elicit declaratives from mothers ("That's a truck!"), whereas object interactions in 24-month-olds, who typically have substantial expressive vocabularies, might elicit interrogatives ("What's that?"). 399 Alternatively, researchers might compare language cascades in infants of different ages but 400 with similar skills—whether the vocalizations of 18- versus 24-month-olds matched on MCDI

vocabulary size elicit similar or different language input from mothers. Finally, we might
compare real-time cascades in infants of the same age but with different skills—such as
whether 18-month-olds who use isolated words versus those who combine words into simple
sentences, elicit different language input from mothers. Comparisons of real-time
contingencies by infant age and skill level provide a unique window into understanding
developmental mechanisms that underpin behavioral change.

Environmental cascades. PLAY's rich array of environmental measures, ranging from 408 distal macro environmental characteristics (e.g., SES, geographic region) to proximal 409 environmental features (e.g., clutter and chaos), will advance understanding of how 410 environmental risks affect everyday opportunities for learning. Researchers might test 411 proximal environmental cascades on the quantity and quality of infants' object interactions 412 and locomotion, for example by coding video home tours (Table 1 VH1) for object 413 availability and using laser measurements of room dimensions (Table 2 NH2). We can relate 414 environmental features of clutter, ambient noise, and so on, to mothers' speech and infants' 415 language development. Researchers can expand the lens of environmental influences to 416 consider how distal macro factors, such as family SES and geo-coded data on neighborhood 417 poverty (Table 2 NH5) relate to proximal environmental measures—objects and space in the 418 home—and in turn infant behaviors, mother behaviors, and infant language and skill. 419

Databrary51, funded by NICHD/NSF, is a digital web-based library for sharing and reusing research videos, clips, and displays. Researchers can reuse shared videos to ask questions beyond the scope of the original study2. They can use shared video clips to learn about procedures and to illustrate findings and displays for teaching3. Sharing is easy. To mitigate the onerous task of curating a dataset after the study is completed, Databrary developed an active curation system. Researchers can use Databrary as a file manager, lab server, and secure backup prior to sharing52. When they are ready to share, they need only click a button. Video contains personally identifiable information, so sharing poses special ethical issues. Advised by ethics experts, IRB and grants/contracts administrators, and legal

counsel, Databrary developed a policy framework 53,54 for sharing identifiable data based on 429 obtaining participants' permission to share and restricting access to authorized researchers 430 under the oversight of their institutions. Since the Databrary website went live in 2014, 580+ 431 researchers (including the launch group) and 245+ affiliates from 330+ institutions around 432 the world are authorized. The repository contains 7820+ hours of video from 7830+ 433 participants. Datavyu8,55 is a powerful, flexible, coding tool that allows researchers to 434 manipulate the temporal-spatial properties of behavior and to tag portions of the video for 435 events and behaviors of interest. With fingertip control over video playback, they can run 436 the video forward and backward at varying speeds ($\pm 1/32$ - 32x normal speed) or jog frame 437 by frame to determine when behaviors began and ended, freeze frames to dissect behavior 438 into its component parts, zoom in/out to focus on details or the larger context, and label 439 behavioral events with categorical and qualitative codes. Each code is time-locked to the video to facilitate tests of behavioral cascades and real-time contingencies based on sequential order, duration, and begin/end times of events. A full scripting language allows researchers to manipulate the spreadsheet, error-check entries, import other data streams, and export data to their specifications for analyses. The latest Datavyu release has new features to reduce the notoriously high cost of transcribing infant and mother speech in noisy contexts, time locked to video, at the utterance level (from the typical 10-12 hours per hour 446 of video to 7-9 hours). 447

Naturally, The creation of a large dataset with many variables raises the possibility
that a particular statistically significant finding may be spurious. In particular, correlational
analyses among non-video questionnaire data require special protection against spurious
findings because of the large number of easily available measures (Table 2). The corpus
includes a summary score for each infant on each instrument, subscores for standard scales,
and raw data for each item. For example, researchers will have access to infants' total
productive vocabulary on the MCDI, the number of words produced within specific
categories (e.g., animal words; action words), and production of each word. Similarly,

researchers will have access to fully processed, ready-to-analyze data on infant temperament, locomotor experience, infant health, environmental chaos, media use, family demographics, and so on. Spurious results and duplication of analyses are especially likely from these "low-hanging fruit."

In contrast to the ready-to-use questionnaire data, analyses of time-locked video codes 460 raise other analytic issues. Data from the foundational coding passes will not be "ready to 461 go." Researchers will need to make decisions about how to process the data—whether to 462 turn categorical codes into frequencies or rates; whether to convert onset/offset times into 463 average durations, latencies from one behavior to another, sequences of behavior, or other 464 analytic constructs. We will encourage individual launch group members to use their 465 expertise and Datavyu training to mine the video corpus (by further coding of natural play 466 and coding of structured play sessions and the home tour). Additional coding passes will be 467 labor intensive, and duplication of coding effort would waste researchers' time. 468

Of course, PLAY's homogenous sampling strategy and cross-sectional design have
limitations. Although the sample will not be nationally representative, it will capture
important demographic variations and can easily grow. With only one session per dyad, we
cannot test stability or predictive validity of behaviors. However, the protocol and codes can
be easily extended to other populations and to longitudinal designs (several launch group
members plan to do this). If labs assigned to data collection or coding cannot fulfill their
tasks, we will replace them.

We will monitor ongoing data collections. If the data are too homogeneous, we will ask some sites to recruit more than their allotment. If a lab's codes are not reliable, we will reassign the videos and retrain the coder.

In conclusion, the PLAY project represents an innovative, synergistic, cross-domain
approach to developmental science that will facilitate scientific discovery, transparency, and
reproducibility we hope for years to come. We will answer fundamental cross-domain
questions about behavioral, environmental, and developmental cascades. We will create the

483 first, large-scale, sharable, reusable, fully transcribed, coded, and curated video corpus of

484 human behavior. We will establish video sharing of procedures, codes, and findings as a new

 $_{\tt 485}$ standard in developmental and behavioral science.
